The Hunnu (Xiongnu) people, also called Huns in Europe, were the largest ethnic group to the north of Han Chinese until the 5th century. The ethno-linguistic affiliation of the Hunnu is controversial among Yeniseian, Altaic, Uralic, and Indo-European. Ancient DNA analyses on the remains of the Hunnu people had shown some clues to this problem. Y chromosome haplogroups of Hunnu remains included Q-M242, N-Tat, C-M130, and R1a1. Recently, we analyzed three samples of Hunnu from Barköl, Xinjiang, China, and determined Q-M3 haplogroup. Therefore, most Y chromosomes of the Hunnu samples examined by multiple studies are belonging to the Q haplogroup. Q is mostly found in Yeniseian and American Indian peoples, suggesting that Hunnu should be in the Yeniseian family. The Y chromosome diversity is well associated with linguistic families in East Asia. According to the similarity in the Y chromosome profiles, there are four pairs of congeneric families, i.e., Austronesian and Tai-Kadai, Mon-Khmer and Hmong-Mien, Sino-Tibetan and Uralic, Yeniseian and Palaesiberian. Between 4,000-2,000 years before present, Tai-Kadai, Hmong-Mien, Sino-Tibetan, and Yeniseian languages transformed into toned analytic languages, becoming quite different from the rest four. Since Hunnu was in the Yeniseian family, all these four toned families were distributed in the inland of China during the transformations. There must be some social or biological factors induced the transformations at that time, which is worth doing more linguistic and genetic researches.

Q-M3 is the major haplogroup of all American Indians. The Barköl sample was most probably Q-M3, and had the STR pattern most similar to that of an aboriginal sample from Argentina. This similarity indicates that American Indians may have the same ancestor with the Hunnu people. Among the Asian ethnic groups, only Yeniseian people’s dominant lineage is haplogroup Q. Therefore, we suggest that Hunnu people were most probably in the Yeniseian family. Moreover, the Hunnu and present Yeniseian languages share many words, such as “son” (kwatha), “horse”(kwetdeh), “stone” (kat), “milk” (mdong), etc. If Hunnu were Yeniseian people, the Yeniseian was then the largest family on the north to Sino-Tibetan in early history of China from around Neolithic Age to 5th century, and thus have been influenced by pre-Chinese culture intensively.

In the early history, the pre-Chinese culture influenced four groups of people, i.e., Sino-Tibetan, Hmong-Mien, Tai-Kadai, and Yeniseian people. Interestingly, only languages of these four groups had transformed into toned analytic languages, leaving their genetic relational populations to be different families. The contour tone systems can only be found in these four families among world languages. There might be some genetic factors contributed to these transformation.
